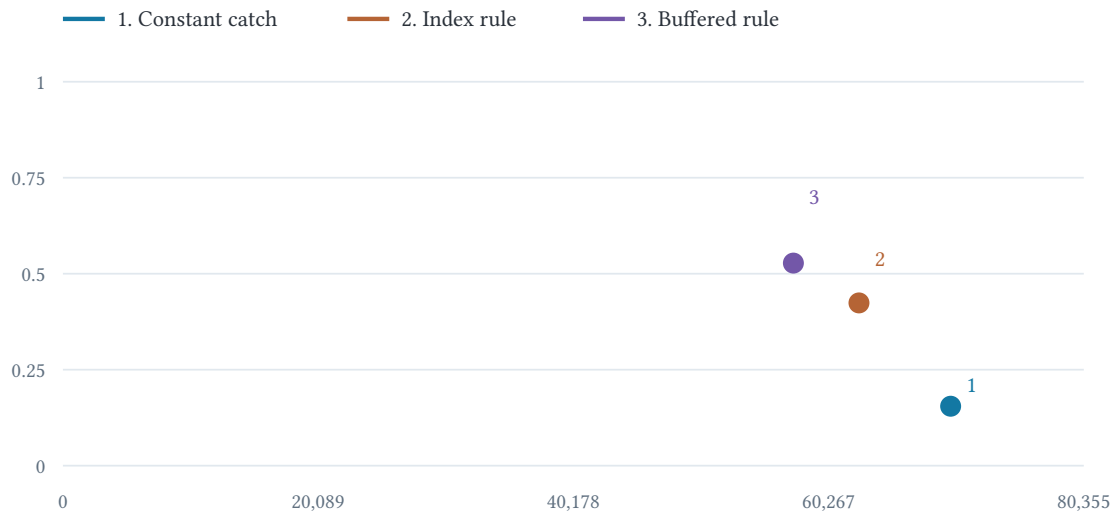
MSE results summary

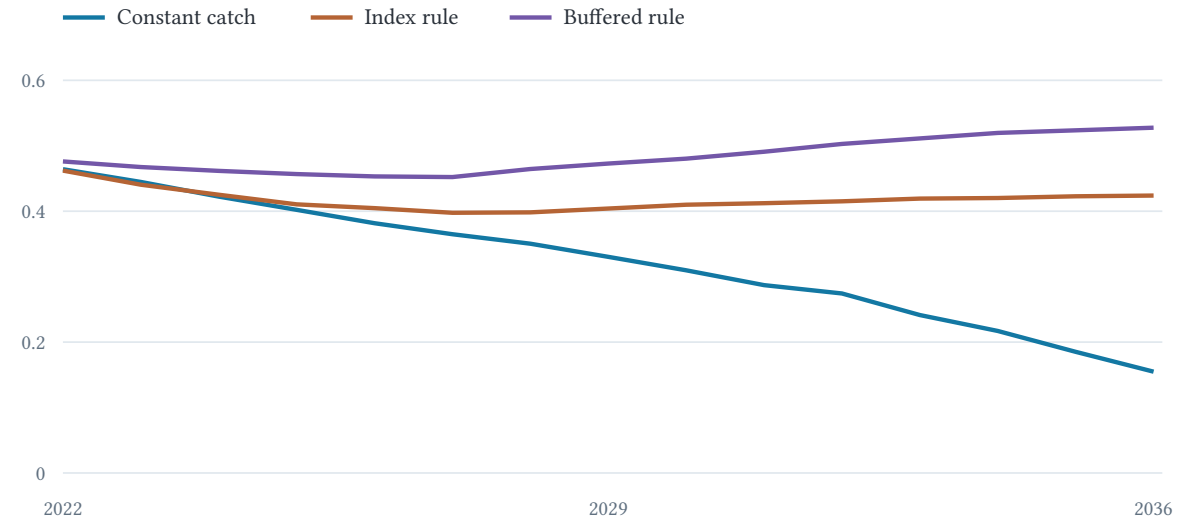
Compare catch, stock condition and catch stability under the same trials.

Catch and final biomass



Mean annual realised catch (tonnes); y: median final B / K

Biomass through time



Median end-of-year B / K

Each point is one rule's saved mean catch and median final biomass. The comparison shows trade-offs and does not rank the rules.

Management rule	Mean catch (t/year)	Final B / K	Trials below 0.2 (%)	Catch change (%)
Constant catch	6.987e+04	0.1548	57.5	1.769
Index rule	6.266e+04	0.4239	0	6.707
Buffered rule	5.75e+04	0.5276	0	6.388

Final biomass is the median across trials. The threshold column counts trials that fell below 0.2 of carrying capacity at any time; 0.2 is an illustrative comparison level. Catch change is annual absolute change relative to mean catch, including the first change from recent catch. Cases and scenarios have equal weight, not estimated probabilities.

The selected Fiji fleet index is not a validated stock-wide abundance index. Using it with stock-wide catches is a teaching assumption.

The shared guardrail caps realised catch at 40% of true starting biomass. Biomass and low-biomass statistics are conditional on that safeguard.

Some requested catches exceeded the simulated harvest limit; metrics use realised catch.
