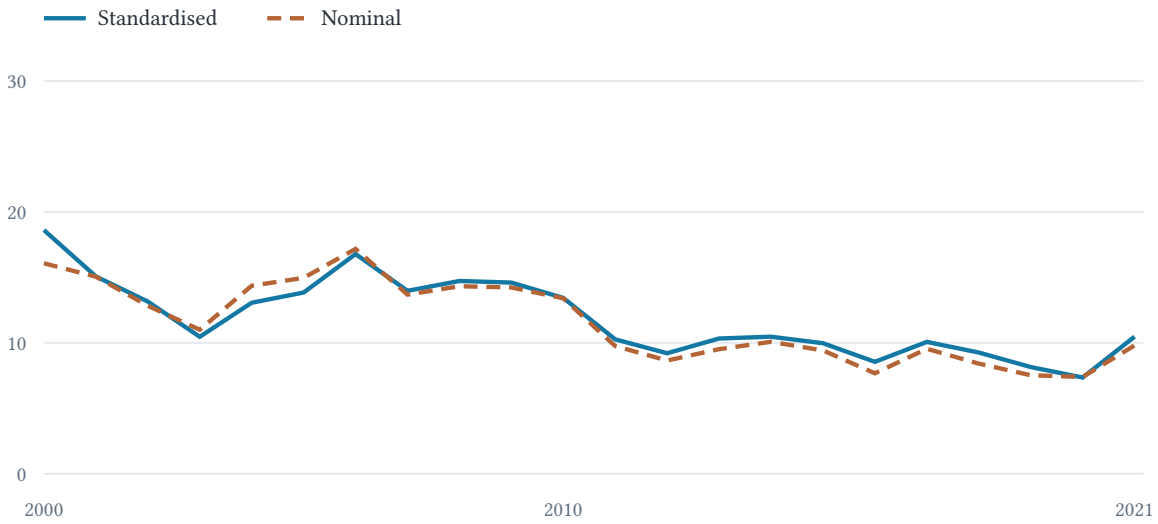
CPUE analysis A

Fiji longline albacore · 2000–2021 · 132 released fleet–cell–quarter records.



Fish per 1,000 hooks

Both curves use the same selected rows; 132 used, 0 excluded; no additional effort filter.

Nominal CPUE = 1,000 × annual fish numbers / annual hooks.

Standardised A holds cell–quarter composition fixed: predict catch at 1,000 hooks in each of the six strata, then average with equal weights.

Quasipoisson GLM: year + cell–quarter stratum · Arithmetic mean of response-scale predictions with equal fixed stratum weights.

These released strata cover the selected fleet. No confidence intervals or stock-wide abundance validation are supplied.

Year	Standardised (fish/1,000 hooks)	Nominal (fish/1,000 hooks)
2000	18.62	16.08
2021	10.47	9.802
